Understanding COVID-19/Novel Coronavirus: What Patients Need to Know

What is COVID-19/coronavirus disease?
The novel SARS-CoV-2 coronavirus that has recently been in the news is a virus that was first identified in December 2019. The virus currently causing coronavirus disease (COVID-19) is not the same as the coronaviruses that commonly circulate among humans and cause mild illness, like the common cold. This virus was first detected in Wuhan City, Hubei Province, China. The first infections were linked to a live animal market, but the virus is now spreading from person-to-person. The Centers for Disease Control and Prevention (CDC) is studying the virus as well as the number of new diagnoses in the United States. The CDC is the original source of information regarding the virus for this fact sheet.

Information regarding COVID-19 is evolving on a daily basis. The latest updates are available on CDC’s COVID-19 website, which may be found the below link:

HOW DOES THE VIRUS SPREAD?
People who are infected with SARS-CoV-2 can spread the virus to others by respiratory droplets. This is now acknowledged to be possible even before symptoms develop. For this reason, social distancing is the best way to prevent spread. COVID-19 is now spreading in communities around the United States (“community spread”) in certain geographic areas. Community spread means people have been infected with the virus in an area, including some who are not sure how or where they became infected. In the healthcare setting, the CDC recommends that these patients be isolated from contact. Patients who do not require admission should remain isolated at home until they are well.

WHAT ARE THE SYMPTOMS OF THE VIRUS?
For confirmed COVID-19 cases, the following symptoms have appeared 2-14 days after exposure in infected people:

- Fever
- Cough
- Shortness of breath
- Loss of taste or smell
- Body aches

Reported illnesses have ranged from mild symptoms to severe illness. The CDC recommends that you contact your doctor immediately if you think you have been exposed to COVID-19 and have symptoms. Please call ahead and take advantage of any phone triage or telehealth options if you think you may have COVID-19 in order to reduce spread of the virus.

WHICH PEOPLE ARE AT HIGHEST RISK?
Older adults, people living with cancer, people currently in treatment, obese patients people that are post-treatment and people who have serious chronic medical conditions (like hypertension, diabetes, respiratory disease or heart disease) may be at higher risk for more serious COVID-19 disease.

If you are at increased risk for COVID-19 complications due to age and/or because you have an underlying medical condition, it is especially important for you to take actions to reduce your risk of exposure (see list below). Some steps you can take include washing your hands well and washing them often with soap. If there’s a community outbreak, try to avoid large crowds and non-essential travel. Make sure to have enough medicine (such as important medications, prescriptions, and over the counter medicine) for up to a month. In addition, you should consult with your own health care provider regarding your health and your treatment, especially if you are currently in active treatment for your lymphoma/CLL.

CAN THE CORONAVIRUS DISEASE BE PREVENTED WITH MEDICAL TREATMENTS?
There is currently no antiviral medication to prevent COVID-19. Vaccines to prevent COVID-19 have recently been granted Emergency Use Authorization (EUA) in the United States. Talk to your health care provider if you are considering other vaccines like the influenza, tetanus or hepatitis.
How can people avoid getting the coronavirus disease?

The best way to prevent illness is to avoid being exposed to this virus. Without a vaccine or antivirals, we have to rely on consistently practicing these CDC recommended actions:

- Follow CDC's recommendations for using a face mask if needed (see CDC website). Improper use of face masks can actually increase your risk of infection so be careful. Masks should be used whenever outside your personal home, car or office; they should be used when people do not routinely live with are in your home, car or office.
- Wash your hands often with soap and water for at least 20 seconds, especially after going to the bathroom; before eating; and after blowing your nose, coughing, or sneezing.
- Clean and disinfect frequently touched objects and surfaces using a regular household cleaning spray or wipe multiple times a day.
- Avoid close contact with people who are sick. Stay at least 6 feet from others whenever possible.
- Avoid crowds, stay home if at all possible.
- Avoid touching your eyes, nose, and mouth.
- Stay home when you are sick and call ahead before seeking treatment unless it is an emergency.
- Cover your cough or sneeze with a tissue, then throw the tissue in the trash. Wash your hands afterwards.
- Clean and disinfect frequently touched objects and surfaces using a regular household cleaning spray or wipe multiple times a day.
- Work from home if you can. If you can't, make sure to disinfect surfaces and clean your hands frequently. Keep your distance from others, even if they seem to be well.

These habits may not seem like enough to protect you from a pandemic, but they are exactly what doctors and hospitals have relied on for years to prevent spread of infection. The CDC also has specific guidance for travelers on the CDC website, but those who are older or have other medical problems should not travel right now unless it is essential.

Before traveling to an appointment to see your health care provider, please call ahead and consult with your doctor about the safest method of travel if you rely on public transportation.

Questions to ask your doctor

People with lymphoma/CLL should consult with their health care provider for more information about monitoring their health for symptoms suggestive of COVID-19, as well as the impact of public health measures currently endorsed by the CDC. Also tell your health care provider (oncologist and primary care physician) about any other health issues or medications you’re current taking. Communicating with all of the members of your health care team will improve the quality of the care you receive.

Vaccine questions and answers

How many vaccines are approved and what how effective is the vaccine?

As of January 2021, two COVID-19 vaccines developed by Pfizer and Moderna have received Emergency Use Authorization from the FDA. Both have an efficacy rate of ~95 percent in clinical trials. Vaccine efficacy measures how well vaccines work to prevent diseases among vaccinated people, when compared to unvaccinated individuals. Studies thus far suggest that receiving two doses of the vaccines are important for achieving the immune response to provide lasting protection. Even after receiving the vaccine, however, it is important to continue following social distancing protocols, handwashing, and use of masks to maximize safety and avoid the spread of infection.

How will COVID-19 vaccines be distributed and where should lymphoma patients go to receive one?

COVID-19 vaccines are being distributed and allocated based on a tiered system. The Center for Disease Control (CDC) has an Advisory Committee on Immunization Practices (ACIP) that has made recommendations for a phased rollout of the vaccine. ACIP has prioritized initial supplies of the vaccine be allocated to healthcare personnel and long-term care facility residents. People with certain underlying medical conditions, such as cancer, are among the groups being prioritized for earlier access to the COVID-19 vaccine. Details of this process will in part be determined by processes and prioritizations established by individual states.

Healthcare professionals will likely be in communication when the vaccine becomes available to you, and you can expect that there will be local announcements via news and other media. Health experts anticipate that these vaccines will become more widely available to the general public in late spring or early summer 2021. Be sure to speak with your oncologist about whether a COVID-19 vaccine might be appropriate for you and details of availability at your medical center or elsewhere in your community.
**SHOULD LYMPHOMA PATIENTS AND SURVIVORS RECEIVE THE COVID-19 VACCINE RIGHT AWAY OR WAIT?**

Most lymphoma patients should receive the COVID-19 vaccine as soon as it is available to them and if recommended by their oncologist. However, given that some lymphoma treatments might affect the efficacy of a vaccine (by impacting the immune system), lymphoma patients and survivors should consult their oncologist or healthcare team prior to receiving the COVID-19 vaccine – particularly if they are in the midst of lymphoma treatment or have had it recently (e.g. within the last 6-12 months). Studies at this point suggest that the COVID-19 vaccines are safe for even those who have underlying health conditions (with the rare exception of some of those with a history of severe allergic reactions).

**CAN THE VACCINE HAVE NEGATIVE EFFECTS TREATMENTS FOR LYMPHOMA?**

There is no evidence (or expectation) at this time that the vaccine will have any impact on lymphoma therapy, nor should lymphoma patients have any increased risk of side effects. Of note, the FDA approved COVID-19 vaccines are NOT “live virus” vaccines (which would be a type that in some cases may be not appropriate for lymphoma patients).

**DOES THE VACCINE HAVE SIDE EFFECTS?**

While many patients will have mild side effects, such as pain at the injection site, fatigue or muscle aches, more serious side effects are rare with either vaccine. You may experience mild reactions after receiving the vaccine that are in keeping with similar symptoms after receiving a flu shot. The most common side effect is soreness at the injection site. Other reactions may include fatigue, headache, muscle aches, joint aches, and, less commonly, fever. These reactions are temporary and may be a sign that your body is building immunity. It is important that any individuals with a history of severe allergic reactions alert the medical team prior to receiving a vaccine, as such reactions can occasionally occur with COVID-19 vaccination. In general, given the risk of exposure to COVID-19 in the community and the potential for severe consequences of infection (including in patients with lymphoma) it is felt that the benefits of vaccination far outweigh the risks.

For additional information and updates on the vaccine, visit the CDC’s website at: https://www.fda.gov/emergency-preparedness-and-response/coronavirus-disease-2019-covid-19/covid-19-vaccines#news
