Peripheral T-cell lymphoma (PTCL) refers to a rare group of different T-cell lymphomas that, together, account for about 5-10 percent of all patients diagnosed with non–Hodgkin Lymphoma (NHL) in the United States.

PTCLs develop in lymphoid tissues outside of the bone marrow such as the lymph nodes, spleen, gastrointestinal tract, and skin. Most PTCLs are aggressive [fast-growing] lymphomas, and include PTCL-not otherwise specified (NOS), angioimmunoblastic T-cell lymphoma (AITL), anaplastic large cell lymphoma (ALCL), enteropathy-associated T-cell lymphoma (EATL), and extranodal natural killer (NK)/T-cell lymphoma (ENKTL). The incidence of PTCL subtypes varies geographically. For more information on PTCL by subtype, please visit the Lymphoma Research Foundation’s (LRF’s) website [visit lymphoma.org/publications].

Peripheral T-Cell Lymphoma, Not Otherwise Specified (PTCL-NOS) is the most common subtype of PTCL, accounting for 30 to 40 percent of PTCL cases in the United States. Patients are usually treated with combination chemotherapy with the intent to cure. Patients may be considered for stem cell transplants at the end of treatment. For more information, view the Understanding the Stem Cell Transplantation Process publication on LRF’s website [visit lymphoma.org/publications].

Anaplastic Large Cell Lymphoma (ALCL) accounts for about 2 percent of lymphomas and about 24 percent of all PTCLs in the United States. Initial symptoms of ALCL can include fever, backache, painless swelling of lymph nodes, loss of appetite, and tiredness. ALCL can be systemic [throughout the body] or cutaneous [affects the skin]. All patients with ALCL express a protein called CD30 on the surface of tumor cells. Systemic ALCL can respond well to an antibody-drug conjugate targeting the CD30 protein. ALCL is potentially curable with brentuximab vedotin [Adcetris] and chemotherapy. Cutaneous ALCL is a form of CTCL and is a less aggressive disease that may be preceded by a rare pre-cancerous condition called lymphomatoid papulosis.

Patients with systemic ALCL are divided into two groups, depending on whether or not the surface of their cells expresses an abnormal form of a protein called anaplastic lymphoma kinase (ALK). The outcome for ALCL varies depending on whether a patient is ALK positive [expresses the protein] or ALK negative [does not express the protein]. ALK-positive disease responds more frequently to standard chemotherapy, putting most patients in long-term remission. Although a majority of patients with ALK-negative ALCL initially respond to treatment, they more frequently relapse within five years and are sometimes treated more aggressively, often with stem cell transplantation. For more information, view the Anaplastic Large Cell Lymphoma [ALCL] fact sheet, please visit LRF’s website [visit lymphoma.org/publications].

Angioimmunoblastic T-Cell Lymphoma (AITL) affects about 15 percent of all patients with PTCL in the United States. Most patients are middle-aged to elderly and are diagnosed with advanced-stage disease. The disease is aggressive and symptoms are common, including high fever, night sweats, skin rash, joint inflammation, and autoimmune disorders such as autoimmune hemolytic anemia (AIHA) and immune thrombocytopenia (ITP). As a result of these autoimmune disorders, the body’s immune system recognizes its own red blood cells (in AIHA) or platelets (in ITP) as foreign and destroys them. Some forms of PTCL that were originally characterized as
PTCL-NOS come from cells of the same origin as AITL. These entities include follicular T-cell lymphoma and PTCL-NOS of T-follicular helper phenotype. These entities are thought to be similar to AITL.

For more information, view the Angioimmunoblastic T-Cell Lymphoma fact sheet on LRF’s website [visit lymphoma.org/publications].

RARE SUBTYPES OF PTCL

Adult T-Cell Leukemia/Lymphoma (ATLL) is a rare and often aggressive T-cell lymphoma that can be found in the blood (leukemia), lymph nodes (lymphoma), skin, or multiple areas of the body. ATLL only occurs in subjects infected with human T-cell lymphotropic virus type 1 (HTLV-1); however, less than 5 percent of individuals with HTLV-1 infection will ever develop ATLL.

The HTLV-1 virus is most common in parts of Japan, the Caribbean, and some areas of South and Central America and Africa. The HTLV-1 virus may be transmitted through sexual contact or exposure to contaminated blood, but it is most often passed from mother to child through the placenta, childbirth by Cesarean section, and breastfeeding. For more information, view the Adult T-Cell Leukemia/Lymphoma fact sheet on LRF’s website [visit lymphoma.org/publications].

Enteropathy-Associated T-Cell Lymphoma (EATL) is an extremely rare and aggressive subtype that appears in the intestines and was previously recognized in two forms: one that is preceded by celiac disease (Type 1 EATL) and one that is not preceded by celiac disease (previously Type 2 EATL, but now classified as a separate disease known as monomorphic epitheliotropic intestinal T-cell lymphoma). Currently, a diagnosis of EATL is only used for cases formerly known as type 1 EATL. Chronic diarrhea and gluten sensitivity frequently precedes EATL. Other symptoms include abdominal pain and weight loss. Very specialized treatments are usually necessary to treat this unique subtype and may include surgery, combination chemotherapy such as CHOP, and stem cell transplantation in select patients.

Extranodal NK/T-Cell Lymphoma develops from NK cells, which are closely related to and often have features that overlap with T cells. This aggressive lymphoma is very rare in the United States, but common in Asia and parts of Latin America. This subtype is associated with the Epstein-Barr virus. It typically originates in the lining of the nose or upper airway at the back of the throat but may appear in the gastrointestinal tract, skin, and other organs (in which case it is referred to as nasal type). Treatment of nasal NK/T-cell lymphoma usually consists of radiation treatments combined with chemotherapy. Chemotherapies for this rare disease include VIPD (etoposide, ifosfamide, cisplatin, and dexamethasone), peg-asparaginase (Oncaspar) or L-asparaginase alone or combined with methotrexate and dexamethasone (AspaMetDex), DeVIC (dexamethasone, etoposide, ifosfamide, and carboplatin), P-GemOX (peg-asparaginase, gemcitabine, oxaliplatin), or SMILE (dexamethasone, methotrexate, ifosfamide, peg-asparaginase, and etoposide).

Hepatosplenic Gamma-Delta T-Cell Lymphoma is an extremely rare and aggressive disease that involves the liver and/or spleen. It can also involve blood and bone marrow. It most often occurs in young adults and is more common in males. This subtype of PTCL can be associated with immunosuppressive treatments. Patients, especially children, treated with immune suppression agents such as azathioprine and infliximab (Remicade) for Crohn’s disease may be more susceptible to this type of PTCL.

As with other rare cancers, patients with EATL, nasal NK/T-cell, or hepatosplenic gamma-delta T-cell lymphomas should discuss whether clinical trials offer potential treatment options with their healthcare team.

TREATMENT OPTIONS

For most subtypes of PTCL, the initial treatment is typically a combination chemotherapy regimen, such as CHOP (cyclophosphamide, doxorubicin, vincristine, and prednisone), CHOEP (cyclophosphamide, doxorubicin, vincristine, etoposide, and prednisone), or other multido drug regimens. Recently, the addition of brentuximab vedotin (Adcetris) to initial chemotherapy significantly improved outcomes for patients with systemic or primary cutaneous ALCCL, and other types of PTCL that have the CD30 marker on their surface. In very specific cases, radiation therapy is given after chemotherapy as a part of first-line treatment. Because many patients with PTCL will relapse, some physicians recommend high-dose chemotherapy followed by an autologous stem cell transplant (patient’s own cells are infused after high-dose chemotherapy) for certain patients. For more information on stem cell transplants, view the Understanding the Stem Cell Transplantation Process publication on LRF’s website [visit lymphoma.org/publications].

Patients with relapsed disease may be treated with combination chemotherapy such as ICE (ifosfamide, carboplatin, and etoposide) or other combination regimens, followed by stem cell transplantation. Increasingly, newer U.S. Food and Drug Administration (FDA)-approved therapies such as crizotinib (Xalkori), belinostat (Beleodaq), pralatrexate (Folotyn), and brentuximab vedotin (Adcetris) are used to treat patients whose lymphoma has come back or never responded to initial therapy. Patients should discuss what treatments are most appropriate for them with their physician.

Romidepsin (Istodax) was previously FDA approved for PTCL and remains available to these patients, as it is National Comprehensive Cancer Network (NCCN) compendium listed. Romidepsin (Istodax) remains FDA approved for CTCL.

TREATMENTS UNDER INVESTIGATION

Many new drugs are being studied in clinical trials for the treatment of PTCL, including:

- Azacitidine (CC-486)
- CAR T-Cell Therapy (AUTO4, ATLCAR,CD30)
- Carfilzomib (Kyprolis)
- Devimistat (CPI 613)
- Durvalumab (Imfinzi)
- Duvelisib (Copiktra)
- GDP (gemcitabine, dexamethasone, and cisplatin)
- Lacutamab (IPH4102)
- Lenalidomide (Revlimid)
Other immunotherapy, targeted therapy, and cellular therapies are also under investigation. It is critical to remember that today’s scientific research is continuously evolving. Treatment options may change as new treatments are discovered and current treatments are improved. Therefore, it is important that patients check with their physician or with LRF for any treatment updates that may have recently emerged.

### Clinical Trials

Clinical trials are crucial in identifying effective drugs and determining optimal doses for patients with lymphoma. Because PTCL is a rare disease and no standard of care is established, clinical trial enrollment is critical for establishing more effective, less toxic treatments. The rarity of the disease also means that the most novel treatments are often available only through clinical trials. Patients interested in participating in a clinical trial should view the Understanding Clinical Trials fact sheet on LRF’s website (visit lymphoma.org/publications), talk to their physician, or contact the LRF Helpline for an individualized clinical trial search by calling (800) 500-9976 or emailing helpline@lymphoma.org.

### Follow-Up

Patients with lymphoma should have regular visits with a physician who is familiar with their medical history and the treatments they have received. Medical tests (such as blood tests, computed tomography [CT] scans, and positron emission tomography [PET] scans) may be required at various times during remission (disappearance of signs and symptoms) to evaluate the need for additional treatment.

Some treatments can cause long-term side effects or late side effects, which can vary based on the duration and frequency of treatments, age, gender, and the overall health of each patient at the time of treatment. A physician will check for these side effects during follow-up care. Visits may become less frequent the longer the disease remains in remission.

Patients and their caregivers are encouraged to keep copies of all medical records and test results as well as information on the types, amounts, and duration of all treatments received. This documentation will be important for keeping track of any side effects resulting from treatment or potential disease recurrences. LRF’s award-winning Focus On Lymphoma mobile app can help patients manage this documentation.

### LRF’s Helpline and Lymphoma Support Network

A lymphoma diagnosis often triggers a range of feelings and concerns. In addition, cancer treatment can cause physical discomfort. The LRF Helpline staff members are available to answer your general questions about a lymphoma diagnosis and treatment information, as well as provide individual support and referrals to you and your loved ones. Callers may request the services of a language interpreter. A part of the Helpline is LRF’s one-to-one peer support programs, Lymphoma Support Network. This program connects patients and caregivers with volunteers who have experience with PTCL, similar treatments, or challenges, for mutual emotional support and encouragement. Patients and loved ones may find this useful whether the patient is newly diagnosed, in treatment, or in remission.

### Mobile App

Focus On Lymphoma is the first mobile application [app] that provides patients and caregivers comprehensive content based on their lymphoma subtype, including PTCL, and tools to help manage their lymphoma such as, keep track of medications and blood work, track symptoms, and document treatment side effects. The Focus On Lymphoma mobile app is available for download for iOS and Android devices in the Apple App Store and Google Play. To learn more about any of these resources, visit our website at lymphoma.org, or contact the LRF Helpline at (800) 500-9976 or helpline@lymphoma.org.

### Lymphoma Care Plan

Keeping your information in one location can help you feel more organized and in control. This also makes it easier to find information pertaining to your care and saves valuable time. LRF offers a Lymphoma Care Plan as a resource for patients and their caregivers. LRF’s Lymphoma Care Plan document organizes information on your health care team, treatment regimen, and follow-up care. You can also keep track of health screenings and any symptoms you experience to discuss with your health care provider during future appointments. The Lymphoma Care Plan document can be accessed by visiting lymphoma.org/publications.
LRF offers a wide range of free resources that address treatment options, the latest research advances, and ways to cope with all aspects of lymphoma and PTCL. LRF also provides many educational activities, including our in-person meetings, and webinars for people with lymphoma. For more information about any of these resources, visit our websites at lymphoma.org/PTCL or lymphoma.org, or contact the LRF Helpline at (800) 500-9976 or helpline@lymphoma.org.

The Understanding Lymphoma series is published by the Lymphoma Research Foundation (LRF) for the purpose of informing and educating readers. Facts and statistics were obtained using published information, including data from the Surveillance, Epidemiology, and End Results (SEER) Program. Because each person’s body and response to treatment is different, no individual should self-diagnose or embark upon any course of medical treatment without first consulting with his or her physician. The medical reviewer, the medical reviewer’s institution, and LRF are not responsible for the medical care or treatment of any individual.
